

Hatchin Unit Economics

Corrected version. Infrastructure now scales with users instead of sitting flat. Generated 2 Aug 2026.

What was corrected. The earlier model held infrastructure flat at \$170 a month across every scale, in the P&L, Runway and Break-even. That is wrong: real infrastructure steps up with users (compute nodes, database compute, email contact tiers, event volume). This version scales it. Everything else (per-user AI cost, payment fees, token prices) was already correct and is unchanged.

Monthly running cost as users grow

Fixed infrastructure and tools only. The per-user AI cost and payment fees are separate and shown in the P&L below.

Signups	Active users (~30% MAU)	Running cost \$/mo	Running cost ₹/mo	Cost per signup	What steps up at this scale
100	~30	\$170	₹14,620	\$1.70	1 small Fly node, Supabase Pro base tier
1,000	~300	\$210	₹18,060	\$0.21	Bigger node with failover, email contact tier grows
10,000	~3,000	\$850	₹73,100	\$0.085	2 to 3 nodes plus Redis, Supabase compute add-on, PITR backups
50,000	~15,000	\$2,250	₹1,93,500	\$0.045	5 to 6 nodes, database read replica, larger email and event tiers
100,000	~30,000	\$4,400	₹3,78,400	\$0.044	10 to 12 nodes, Supabase Team plus replica, scaled monitoring

The point: 10x the users from 10k to 100k costs only about 5x the infrastructure. It grows sub-linearly, which is why the margin widens at scale. Flat items (domain, uptime, your own dev usage) barely move; compute, database and email are what climb.

What makes up the 10,000-signup figure (\$850)

Line item	\$/mo	Why
Fly.io app hosting (2 to 3 performance nodes)	180	WebSockets need more than one node now
Supabase Pro plus compute add-on	110	8GB base exceeded, plus egress
Point-in-time-recovery backups	100	real add-on, your open pre-launch item
Marketing email (~10k contacts)	150	priced per contact
Sentry and PostHog	130	event volume past the free tiers
Redis (WebSocket pub/sub)	30	needed once there is more than one node
Transactional email, backups, CDN, logs, misc	150	
Total to keep it live	\$850	₹73,100 per month

Full economics on the corrected model

Base case: paid conversion 4% of signups, Pro at \$19/mo, active users 30% of signups, B2C only (B2B seats are upside, not counted). Gross profit here is revenue minus AI cost, payment fees and infrastructure. It excludes team salaries and corporate tax, which are a separate layer.

Signups	Paying (4%)	Revenue \$/mo	AI + payment \$/mo	Infra \$/mo	Gross profit \$/mo	Margin
100	4	\$76	\$11	\$170	-\$105	loss
1,000	40	\$760	\$106	\$210	\$444	58%
10,000	400	\$7,600	\$1,061	\$850	\$5,689	75%
50,000	2,000	\$38,000	\$5,304	\$2,250	\$30,446	80%
100,000	4,000	\$76,000	\$10,608	\$4,400	\$60,992	80%

Gross profit in rupees: 1k signups about ₹38,200/mo, 10k about ₹4,89,000/mo, 50k about ₹26.2 lakh/mo, 100k about ₹52.4 lakh/mo. You cross from loss to profit between 100 and 1,000 signups, and margin expands toward ~80% as fixed infrastructure amortises across more paying users.

Assumptions and confidence

- Solid, real published prices. Supabase Pro \$25, Fly base, Sentry Team \$26, Stripe 2.9% + \$0.30, DeepSeek and Gemini token rates. These are sourced.
- Estimated, within real vendor ranges. Every scaled infrastructure number above. Node counts assume 3 to 5% of active users are concurrent on WebSockets at peak. A load test would replace the estimate with a measured fact.
- Revenue basis to confirm. Modelled B2C only at \$19 Pro because the prior sheet implied heavy B2B revenue I could not reconstruct cleanly. If your real plan leans on B2B seats at a higher price, revenue and profit rise materially and I should use your actual numbers.
